

# Final Lab Report

## Bluetooth Motor Control System

ME-4370 - Stephen Canfield

# 1 Introduction

In this final lab, the objective was to use two microcontrollers connected through Bluetooth to control two "fans". The fans are two motors that are speed controlled with potentiometers. Additionally, two sensors are used to turn the motors off at any moment given object detection. This system demonstrates the remote control of motors and the use of object detection using proximity and motion sensors for a safety systems.

Several analog to digital conversions take place to operate this system. The potentiometers are analog inputs converted into a digital number between 0 and 250. Where 0 is the motor stopped and 250 is the motor at max speed. A total of two potentiometers, each controls one of the two motors.

The sensors are also analog inputs converted into a digital signals. Two sensors were used. The SHARP 2Y0A02F18 IR distance sensor and the HC-SR501 IR motion sensor. The distance sensor was used to turn off motor1 if it detected an object within 20 cm. The motion sensor was used to turn off motor2 if motion was detected in the sensors field of view.

Two HM-10 bluetooth modules were used to communicate data from system to system. The bluetooth modules were configured to pair with one another and with the serial UART TX and RX connection with the microcontroller.

Demonstration of this system can be viewed on YouTube [1].

This Lab report should contain the following:

1. Cover page (1 page) Include title, date, authors, signature, recipient
2. Introduction
3. Procedure for design
4. Procedure for development / construction
5. Assessment
6. Conclusions
7. References
8. Appendix 1: Circuit diagram
9. Appendix 2: Program Flowchart
10. Appendix 3: Program listing

# 2 Design

The electrical components used in the system are as follows:

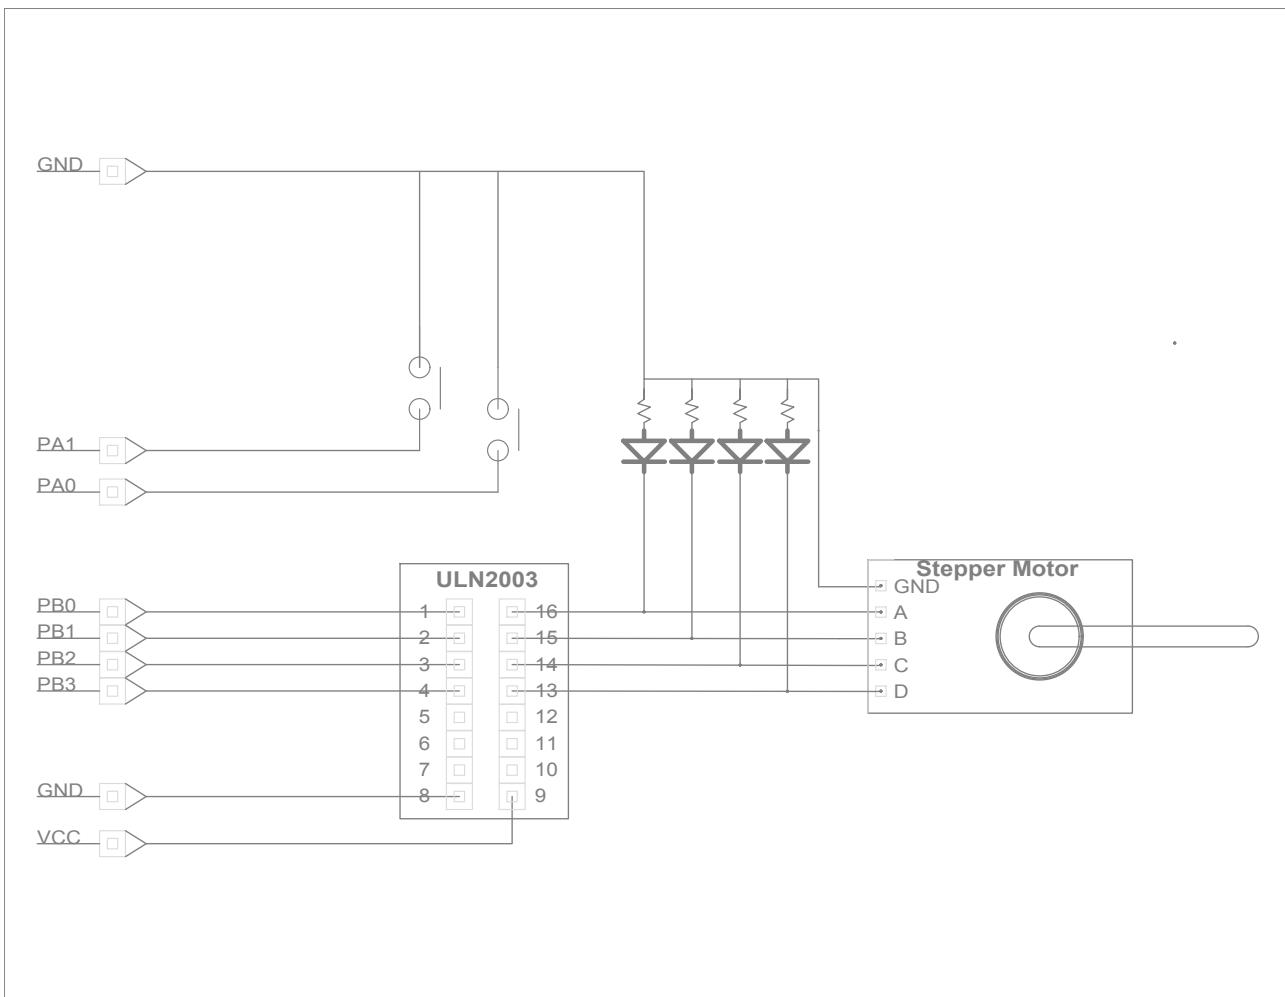

Figure 1: Circuit Diagram

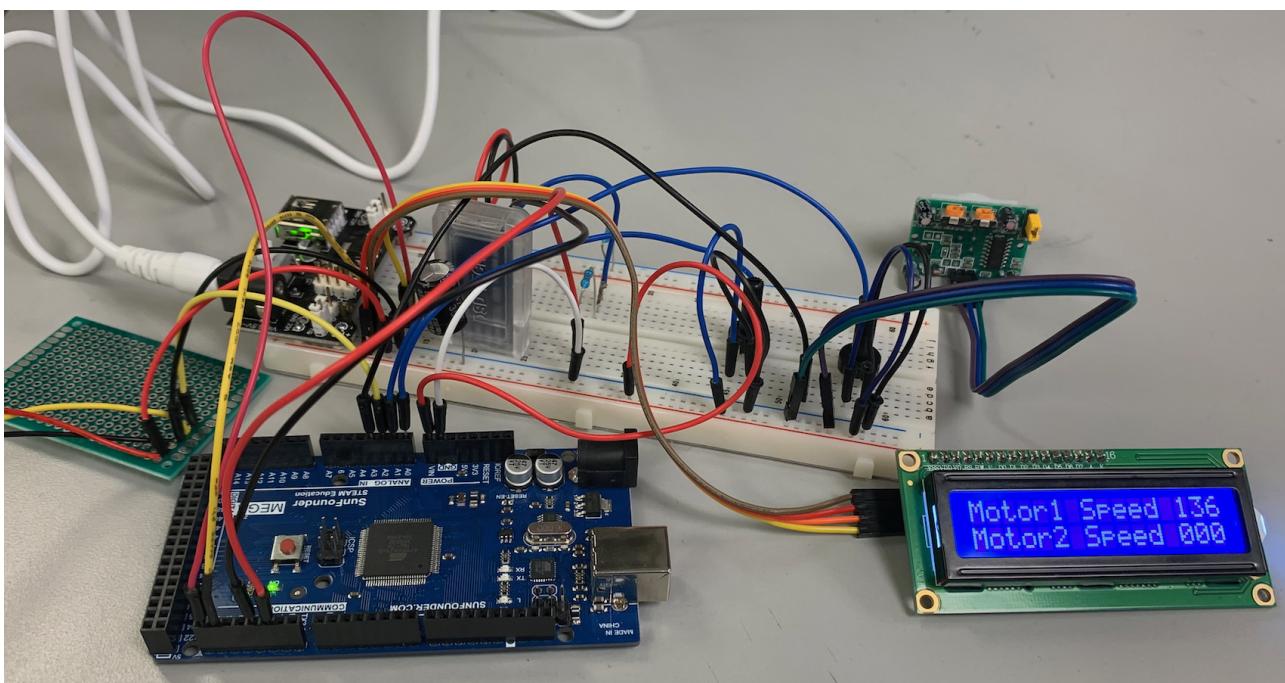

Figure 2: Breadboard and Connections

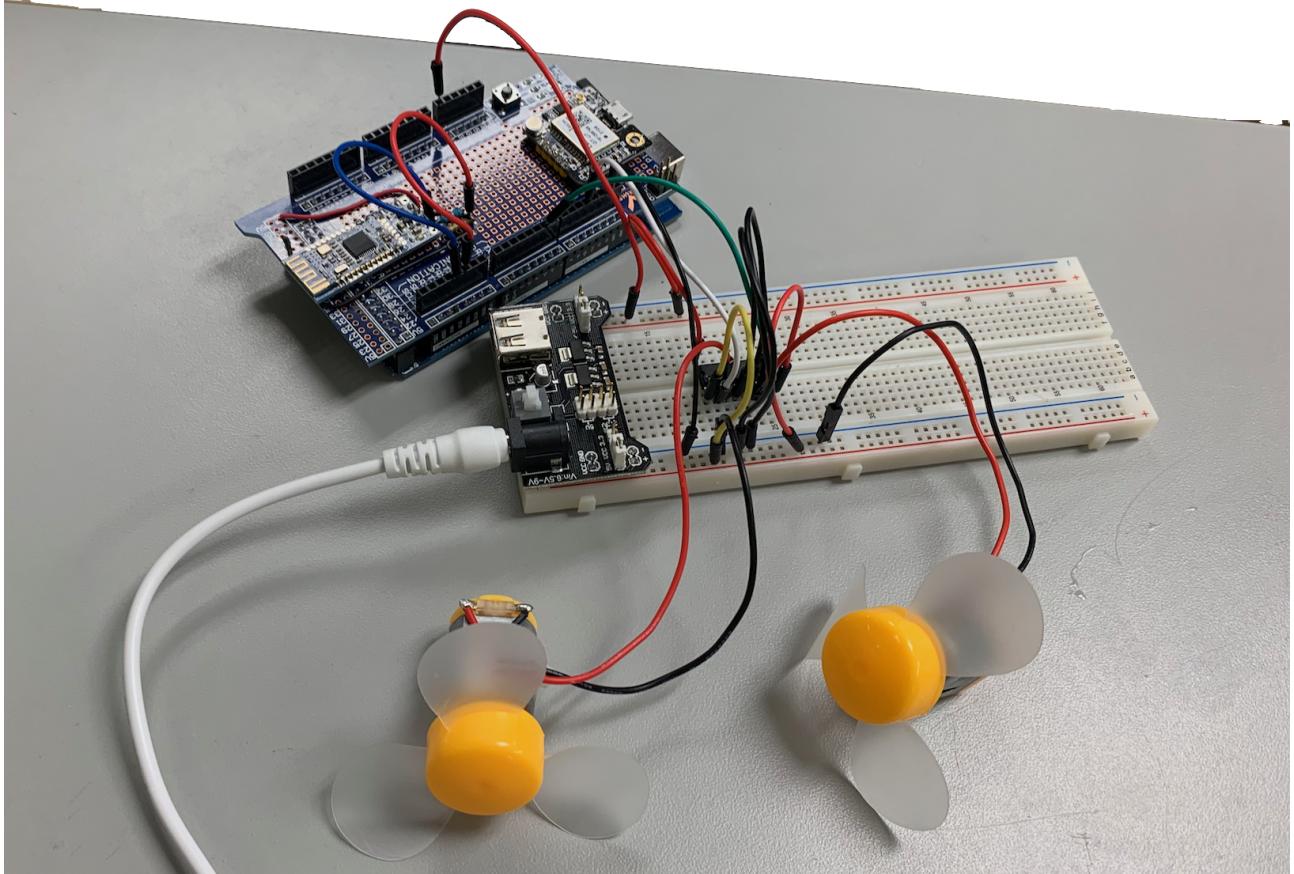

Figure 3: Breadboard and Connections

Quantity	Model	Description
2	Arduino Atmega 2560	Microcontroller
2	HM-10	Low Energy Bluetooth modules
2	10k Generic Potentiometer	Variable Resistor
2	Gikfun DC Motor	3-6 Volt DC Motor

### 3 Development

The construction in this project is constructed as shown in figures ??, ??, and ???. The IC chip in ?? is an L293D motor driver; reference the data sheet for the pinout.

### 4 Assessment

To test the system, we waved an object in front of the motion sensor to see if the corresponding motor turned off. We also waved an object in front of the IR distance sensor to see if the corresponding motor turned off. At first the system did not work, so we made adjustments in

the code. We initially used 8-bit PWM, but it did not work. We used 10-bit fast PWM and it worked. Since the bluetooth module can only send a byte at a time, we had to scale the 10-bit number received from the ADC to an 8-bit number. To do this, we divided the 10-bit number by 4. When the Arduino that controls the motors received a byte from the bluetooth communication, it multiplied the data by 4 to unscale the number.

## 5 Conclusions

## 6 References

## 7 Appendix i: Circuit diagram

## 8 Appendix ii: Program Flowchart

## 9 Appendix iii: Source Code - Remote Control

This section contains the source code from the microcontroller reading potentiometers and the sensors to control the speed of the motors, and then sending the speeds over bluetooth to the motor control microcontroller.
